[in package DREF]

## 1 Links and Systems

Here is the [official repository](#) and the [HTML documentation](#) for the latest version.

- **[system] "dref"**
  - *Version:* 0.5.0
  - *Description:* Reify definitions, provide portable access to arglists, docstrings and source locations in an extensible framework.
  - *Long Description:* `defun` defines a first-class object: a `function`. `defvar` does not. The DRef library provides a way to refer to all definitions and smooths over the differences between implementations. This system has minimal dependencies. It autoloads the `dref/full` `asdf:system`.
  - *Licence:* MIT, see COPYING.
  - *Author:* Gábor Melis
  - *Mailto:* [mega@retes.hu](mailto:mega@retes.hu)
  - *Homepage:* <http://github.com/melisgl/dref/>
  - *Bug tracker:* <https://github.com/melisgl/dref/issues>
  - *Source control:* `GIT`
  - *Depends on:* `autoload`, `mgl-pax-bootstrap`, `named-readtables`, `pythonic-string-reader`
  - *Auto depends on:* `dref/full`
  - *Defsystem depends on:* `autoload`
- **[system] "dref/full"**
  - *Description:* DRef with everything loaded. There should be no need to explicitly load this system (or depend on it) because it is autoloaded as necessary by all publicly accessible functionality in `dref`.
  - However, to get the dependencies, install this system.
  - For a discussion of conditional dependencies, see [Backends](#).
  - *Depends on:* `alexandria`, `closer-mop`, `dref`, `mgl-pax`, `sb-introspect(?)`, `swank(?)`

- *Defsystem depends on:* autoload

## 2 Introduction

*What if definitions were first-class objects?*

Some **defining forms** do not create first-class **objects**. For example, **defun** creates **function** objects, but **defvar** does not create variable objects, as no such thing exists in Common Lisp. The main purpose of this library is to fill this gap with the introduction of **dref** objects:

```
(defvar *my-var* nil
  "This is my var.")
(dref '*my-var* 'variable)
==> #<DREF *MY-VAR* VARIABLE>
```

drefs just package up a **name** (*\*my-var\**) and a **locative** (*variable*) then check that the definition actually exists:

```
(dref 'junk 'variable)
.. debugger invoked on LOCATE-ERROR:
.. Could not locate JUNK VARIABLE.
```

The **Basic Operations** on definitions in DRef are **arglist**, **docstring** and **source-location**.

```
(docstring (dref '*my-var* 'variable))
=> "This is my var."
=> NIL
```

For definitions associated with objects, the definition can be **located** from the object:

```
(locate #'print)
==> #<DREF PRINT FUNCTION>
```

These objects designate their definitions, so `(docstring #'print)` works. Extending DRef and these operations is possible through **Defining Locative Types**. It is also possible to define new operations. For example, PAX makes `pax:document` extensible through `pax:document-object*`.

Finally, existing definitions can be queried with **definitions** and **dref-*apropos***:

```
(definitions 'dref-ext:arglist*)
==> (#<DREF ARGLIST* GENERIC-FUNCTION>
--> #<DREF ARGLIST* (METHOD (CLASS-DREF))>
--> #<DREF ARGLIST* (METHOD (COMPILER-MACRO-DREF))>
--> #<DREF ARGLIST* (METHOD (FUNCTION-DREF))>
--> #<DREF ARGLIST* (METHOD (LAMBDA-DREF))>
--> #<DREF ARGLIST* (METHOD (MACRO-DREF))>
--> #<DREF ARGLIST* (METHOD (METHOD-DREF))>
--> #<DREF ARGLIST* (METHOD (SETF-DREF))>
--> #<DREF ARGLIST* (METHOD (TYPE-DREF))> #<DREF ARGLIST* (METHOD (DREF))>
--> #<DREF ARGLIST* (METHOD (MGL-PAX::GO-DREF))>
--> #<DREF ARGLIST* (METHOD (T))>
--> #<DREF ARGLIST* (UNKNOWN
```

```

--> (DECLAIM ARGLIST*
--> (FTYPE))>)

(dref-apropos 'locate-error :package :dref)
==> (#<DREF LOCATE-ERROR CONDITION> #<DREF LOCATE-ERROR FUNCTION>)

(dref-apropos "ate-err" :package :dref :external-only t)
==> (#<DREF LOCATE-ERROR CONDITION> #<DREF LOCATE-ERROR FUNCTION>)

```

### 3 References

After the [Introduction](#), here we get into the details. Of special interest are:

- The `xref` function to construct an arbitrary [reference](#) without any checking of validity.
- `locate` and `dref` to look up the [definition](#) of an object (e.g. `#'print`) or a [reference](#) (e.g. `(xref 'print 'function)`).
- `resolve` to find the first-class (non-`xref`) object the definition refers to, if any.

The [Basic Operations](#) (`arglist`, `docstring`, `source-location`) know how to deal with references (discussed in the [Extending DRef](#)).

- **[class]** `xref`

An `xref` (cross-reference) is a [reference](#). It may represent some kind of [definition](#) of its [name](#) in the context given by its [locative](#). The definition may not exist and the locative may even be [invalid](#). The subclass `dref` represents definitions that exist.

- **[function]** `xref` *name locative*

A shorthand for `(make-instance 'xref :name name :locative locative)` to create `xref` objects. It does no error checking: the [locative-type](#) of `locative` need not be defined, and the [locative-args](#) need not be valid. Use `locate` or the `dref` function to create `dref` objects.

- **[function]** `xref=` *xref1 xref2*

See if `xref1` and `xref2` have the same [xref-name](#) and [xref-locative](#) under `equal`. Comparing like this makes most sense for `drefs`. However, two `xrefs` different under `xref=` may denote the same `drefs`.

- **[class]** `dref` *xref*

`drefs` can be thought of as [definitions](#) that actually exist, although changes in the system can invalidate them (for example, a `dref` to a function definition can be invalidated by `fmakunbound`). `drefs` must be created with `locate` or the `dref` function.

Two `drefs` created in the same [dynamic environment](#) denote the same thing if and only if they are `xref=`.

- **[function]** `locate` *object &optional (errorp t)*

Return a [dref](#) representing the [definition](#) of object.

object must be a supported first-class object, a dref, or an [xref](#):

```
(locate #'print)
==> #<DREF PRINT FUNCTION>
```

```
(locate (locate #'print))
==> #<DREF PRINT FUNCTION>
```

```
(locate (xref 'print 'function))
==> #<DREF PRINT FUNCTION>
```

When object is a dref, it is simply returned.

Else, a `locate-error(0 1)` is signalled if object is an [xref](#) with an invalid [locative](#), or if no corresponding definition is found. If `errorp` is `nil`, then `nil` is returned instead.

```
(locate (xref 'no-such-function 'function))
.. debugger invoked on LOCATE-ERROR:
.. Could not locate NO-SUCH-FUNCTION FUNCTION.
.. NO-SUCH-FUNCTION does not name a function.
```

```
(locate (xref 'print '(function xxx)))
.. debugger invoked on LOCATE-ERROR:
.. Could not locate PRINT #'XXX.
.. Bad arguments (XXX) for locative FUNCTION with lambda list NIL.
```

```
(locate "xxx")
.. debugger invoked on LOCATE-ERROR:
.. Could not locate "xxx".
```

Use the [xref](#) function to construct an [xref](#) without error checking.

See [Extending locate](#).

- **[function]** `dref` *name locative &optional (errorp t)*

Shorthand for `(locate (xref name locative) errorp)`.

- **[function]** `resolve` *object &optional (errorp t)*

If object is an [xref](#), then return the first-class object associated with its definition if any. Return object if it's not an [xref](#). Thus, the value returned is never an [xref](#). The second return value is whether resolving succeeded.

```
(resolve (dref 'print 'function))
==> #<FUNCTION PRINT>
=> T
```

```
(resolve #'print)
==> #<FUNCTION PRINT>
=> T
```

If object is an xref, and the definition for it cannot be `located`, then `locate-error(0 1)` is signalled.

```
(resolve (xref 'undefined 'variable))  
.. debugger invoked on LOCATE-ERROR:  
.. Could not locate UNDEFINED VARIABLE.
```

If there is a definition, but there is no first-class object corresponding to it, then `resolve-error(0 1)` is signalled or `nil` is returned depending on `errorp`:

```
(resolve (dref '*print-length* 'variable))  
.. debugger invoked on RESOLVE-ERROR:  
.. Could not resolve *PRINT-LENGTH* VARIABLE.
```

```
(resolve (dref '*print-length* 'variable) nil)  
=> NIL  
=> NIL
```

`resolve` is a partial inverse of `locate`: if a `dref` is resolveable, then `locate`ing the object it resolves to recovers the `dref` equivalent to the original (`xref=` and of the same type but not `eq`).

Can be extended via `resolve*`.

- [condition] `locate-error` *error condition-context-mixin*

Signalled by `locate` when the definition cannot be found, and `errorp` is true.

- [condition] `resolve-error` *error condition-context-mixin*

Signalled by `resolve` when the object defined cannot be returned, and `errorp` is true.

### 3.1 Dissecting References

- [reader] `xref-name` *xref* (:name)

The `name` of the reference.

- [reader] `xref-locative` *xref* (:locative)

The `locative` of the reference.

The `locative` is normalized by replacing single-element lists with their only element:

```
(xref 'print 'function)  
==> #<XREF PRINT FUNCTION>
```

```
(xref 'print '(function))  
==> #<XREF PRINT FUNCTION>
```

- [reader] `dref-name` *dref*

The same as `xref-name`, but only works on `drefs`. Use it as a statement of intent.

- [reader] `dref-locative` *dref*

The same as `xref-locative`, but only works on `drefs`. Use it as a statement of intent.

- **[reader]** `dref-origin` *dref*

The object from which `locate` constructed this `dref`. `dref-origin` may have `presentation` arguments, which are not included in `locative-args` as is the case with the `initform` argument of the `variable` locative:

```
(dref '*standard-output*' '(variable "see-below"))
==> #<DREF *STANDARD-OUTPUT* VARIABLE>

(dref-origin (dref '*standard-output*' '(variable "see-below")))
==> #<XREF *STANDARD-OUTPUT* (VARIABLE "see-below")>
```

The `initform` argument overrides the global binding of `*standard-output*` when it's `pax:documented`:

```
(first-line
 (pax:document (dref '*standard-output*' '(variable "see-below"))
               :stream nil))
=> "- [variable] *STANDARD-OUTPUT* \"see-below\""
```

- **[function]** `locative-type` *locative*

Return `locative type` of the `locative` locative. This is the first element of `locative` if it's a list. If it's a symbol, it's that symbol itself.

- **[function]** `locative-args` *locative*

Return the `rest` of `locative` locative if it's a list. If it's a symbol, then return `nil`. See `locative`.

The following convenience functions are compositions of `{locative-type, locative-args}` and `{xref-locative, dref-locative}`.

- **[function]** `xref-locative-type` *xref*
- **[function]** `xref-locative-args` *xref*
- **[function]** `dref-locative-type` *dref*
- **[function]** `dref-locative-args` *dref*

## 3.2 References Glossary

- **[glossary-term]** `reference`

A reference is a `name` plus a `locative`, and it identifies a possible definition. References are of class `xref`. When a reference is a `dref`, it may also be called a `definition`.

- **[glossary-term]** `definition`

A definition is a [reference](#) that identifies a concrete definition. Definitions are of class [dref](#). A definition [resolves](#) to the first-class object associated with the definition if such a thing exists, and [locate](#) on this object returns the canonical [dref](#) object that's unique under [xref=](#).

The kind of a definition is given by its [locative type](#). There is at most one definition for any given [name](#) and locative type. Equivalently, there can be no two definitions of the same [dref-name](#) and [dref-locative-type](#) but different [dref-locative-args](#).

- **[glossary-term]** [name](#)

Names are symbols, strings and nested lists of the previous, which name [functions](#), [types](#), [packages](#), etc. Together with [locatives](#), they form [references](#).

See [xref-name](#) and [dref-name](#).

- **[glossary-term]** [locative](#)

Locatives specify a *type* of definition such as [function](#) or [variable](#). Together with [names](#), they form [references](#).

In their compound form, locatives may have arguments (see [locative-args](#)) as in `(method (number))`. In fact, their atomic form is shorthand for the common no-argument case: that is, `function` is equivalent to `(function)`.

A locative is valid if it names an existing [locative type](#) and its `locative-args` match that type's lambda-list (see [define-locative-type](#)).

```
(arglist (dref 'method 'locative))
=> (&REST QUALIFIERS-AND-SPECIALIZERS)
=> :DESTRUCTURING
```

See [xref-locative](#) and [dref-locative](#).

- **[glossary-term]** [locative type](#)

The locative type is the part of a [locative](#) that identifies what kind of definition is being referred to. This is always a symbol.

Locative types are defined with [define-locative-type](#) or [define-pseudo-locative-type](#). See [Basic Locative Types](#) for the list locative types built into DRef, and PAX Locatives for those in PAX.

Also, see [locative-type](#), [xref-locative-type](#), [dref-locative-type](#), [Defining Locative Types](#).

- **[glossary-term]** [presentation](#)

[references](#) may have arguments (see [Defining Locative Types](#)) that do not affect the behaviour of [locate](#) and the [Basic Operations](#), but which may be used for other, "presentation" purposes. For example, the [variable](#) locative's `initform` argument is used for presentation by `pax:document`. Presentation arguments are available via [dref:dref-origin](#) but do not feature in [dref-locative](#) to ensure the uniqueness of the definition under [xref=](#).

## 4 dtypes

dtypes generalize [locative types](#) the same way Lisp types generalize [classes](#). A dtype is either

- a [locative type](#) such as [function](#), [type](#) and [clhs](#), or
- a full [locative](#) such as [\(method \(number\)\)](#) and [\(clhs section\)](#), or
- [nil](#) (the empty dtype) and [t](#) (that encompasses all [lisp-locative-types](#)), or
- named with [define-dtype](#) (such as [pseudo](#) and [top](#)), or
- a combination of the above with [and](#), [or](#) and [not](#), or
- a [member\(0 1\)](#) form with [locateable](#) definitions, or
- a [satisfies](#) form with the name of a function that takes a single [definition](#) as its argument.

dtypes are used in [definitions](#) and [dref-apropos](#) to filter the set of definitions as in

```
(definitions 'print :dtype '(not unknown))  
==> (#<DREF PRINT (CLHS FUNCTION)> #<DREF PRINT FUNCTION>)
```

```
(dref-apropos "type specifier" :dtype 'pseudo)  
==> (#<DREF "1.4.4.6" #1=(CLHS SECTION)> #<DREF "1.4.4.6.1" #1#>  
--> #<DREF "1.4.4.6.2" #1#> #<DREF "1.4.4.6.3" #1#>  
--> #<DREF "1.4.4.6.4" #1#> #<DREF "4.2.3" #1#>  
--> #<DREF "atomic type specifier" #2=(CLHS GLOSSARY-TERM)>  
--> #<DREF "compound type specifier" #2#>  
--> #<DREF "derived type specifier" #2#> #<DREF "type specifier" #2#>)
```

- **[macro]** `define-dtype` *name lambda-list &body body*

Like [deftype](#), but it may expand into other dtypes.

The following example defines `method*` as the locative [method](#) without its direct locative subtypes.

```
(define-dtype method* () '(and method (not reader) (not writer)))
```

See [dtypep](#) for the semantics and also the locative [dtype](#).

- **[dtype]** `top`

This is the top of the dtype hierarchy, much like `t` for Lisp types. It expands to [\(or t pseudo\)](#). While `t` matches every normal Lisp object and objectless definitions present in the running Lisp (see [lisp-locative-types](#)), `top` matches even pseudo definitions (see [pseudo-locative-types](#)).

- **[dtype]** `pseudo`

This is the union of all [pseudo-locative-types](#). It expands to [\(or ,@\(pseudo-locative-types\)\)](#).

- **[function]** `dtypep` *dref dtype*

See if dref is of dtype.

- *Atomic locatives*: If dtype is a *locative type*, then it matches definitions with that locative type and its locative subtypes.

Because *constant* is defined with *variable* among its *locative-supertypes*:

```
(dtypep (dref 'pi 'constant) 'variable)
=> T
```

```
(dtypep (dref 'number 'class) 'type)
=> T
```

It is an error if dtype is an *atom(0 1)* but not a *locative type*. On the other hand, (the empty) argument list of atomic locatives is not checked even if having no arguments makes them *invalid*.

- *Compound locatives*: Locatives in their compound form are validated and must match exactly (under *equal*, as in *xref=*).

```
(defparameter *d* (dref 'dref* '(method (t t t))))
(defparameter *d2* (dref 'dref* '(method :around (t t t))))
(dtypep *d* 'method)
=> T
(dtypep *d* '(accessor))
.. debugger invoked on SIMPLE-ERROR:
.. Bad arguments NIL for locative ACCESSOR with lambda list
↪ (CLASS-NAME).
(dtypep *d* '(method (t t t)))
=> T
(dtypep *d2* '(method (t t t)))
=> NIL
```

- dtype may be constructed with *and*, *or* and *not* from Lisp types, locative types, full locatives and named dtypes:

```
(dtypep (dref 'locate-error 'condition) '(or condition class))
=> T
(dtypep (dref nil 'type) '(and type (not class)))
=> T
```

- For (member &rest objs), each of objs is *located* and dref is matched against them with *xref=*:

```
(dtypep (locate #'print) `(member ,#'print))
=> T
```

- For (satisfies pred), the predicate pred is funcalled with dref.
- dtype may be named by *define-dtype*:

```
(dtypep (locate #'car) 'top)
=> T
```

## 5 Listing Definitions

- **[function]** `definitions` *name &key (dtype t) (sort t)*

List all definitions of `name` that are of dtype as `drefs`.

Just as `(dref name locative)` returns the canonical definition, the `dref-names` of returned by definitions may be different from `name`:

```
(definitions "PAX")  
==> (#<DREF "MGL-PAX" PACKAGE>)
```

```
(definitions 'mgl-pax)  
==> (#<DREF "MGL-PAX" PACKAGE> #<DREF "mgl-pax" ASDF/SYSTEM:SYSTEM>)
```

Similarly, `dref-locative-type` may be more made more specific:

```
(definitions 'dref:locate-error :dtype 'type)  
==> (#<DREF LOCATE-ERROR CONDITION>)
```

If sort, the returned list is ordered according to `sort-references`.

Can be extended via `map-definitions-of-name`.

- **[function]** `dref-apropos` *name &key package external-only case-sensitive (dtype t) (sort t)*

Return a list of `drefs` corresponding to existing definitions that match the various arguments. First, `(dref-apropos nil)` lists all definitions in the running Lisp and maybe more (e.g. `mgl-pax:clhs`). Arguments specify how the list of definitions is filtered.

`dref-apropos` itself is similar to `cl:apropos-list`, but

- it finds `definitions` not `symbols`,
- it supports an extensible definition types, and
- filtering based on them.

PAX has a live browsing frontend.

Roughly speaking, when `name` or `package` is a symbol, it must match the whole `name` of the definition:

```
(dref-apropos 'method :package :dref :external-only t)  
==> (#<DREF METHOD CLASS> #<DREF METHOD LOCATIVE>)
```

On the other hand, when `name` or `package` is a string(0 1), they are matched as substrings to the definition's name `princ-to-stringed`:

```
(dref-apropos "method" :package :dref :external-only t)  
==> (#<DREF SETF-METHOD LOCATIVE> #<DREF METHOD CLASS>  
-> #<DREF METHOD LOCATIVE> #<DREF METHOD-COMBINATION CLASS>  
-> #<DREF METHOD-COMBINATION LOCATIVE>)
```

Definitions that are not of dtype (see `dtypep`) are filtered out:

```
(dref-apropos "method" :package :dref :external-only t :dtype 'class)
==> (#<DREF METHOD CLASS> #<DREF METHOD-COMBINATION CLASS>)
```

When package is :none, only non-symbol *names* are matched:

```
(dref-apropos "dref" :package :none)
==> (#<DREF "DREF" PACKAGE> #<DREF "DREF-EXT" PACKAGE>
--> #<DREF "DREF-TEST" PACKAGE> #<DREF "dref" ASDF/SYSTEM:SYSTEM>
--> #<DREF "dref/full" ASDF/SYSTEM:SYSTEM>
--> #<DREF "dref/test" ASDF/SYSTEM:SYSTEM>
--> #<DREF "dref/test-autoload" ASDF/SYSTEM:SYSTEM>)
```

The exact rules of filtering are as follows. Let *c* be the *name* of the candidate definition from the list of all definitions that we are matching against the arguments and denote its string representation (*princ-to-string* *c*) with *p*. Note that *princ-to-string* does not print the package of symbols. We say that two strings *match* if case-sensitive is nil and they are *equalp*, or case-sensitive is true and they are *equal*. case-sensitive affects *substring* comparisons too.

- If name is a symbol, then its *symbol-name* must *match* *p*.
- If name is a string, then it must be a *substring* of *p*.
- If package is :any, then *c* must be a symbol.
- If package is :none, then *c* must *not* be a symbol.
- If package is not nil, :any or :none, then *c* must be a symbol.
- If package is a *package*, it must be *eq* to the *symbol-package* of *c*.
- If package is a symbol other than nil, :any and :none, then its *symbol-name* must *match* the *package-name* or one of the *package-nicknames* of *symbol-package* of *c*.
- If package is a string, then it must be a *substring* of the *package-name* of *symbol-package* of *c*.
- If *external-only* and *c* is a symbol, then *c* must be external in a matching package.
- *dtype* matches candidate definition *d* if (*dtypep* *d* *dtype*).

If *sort*, the returned list is ordered according to *sort-references*.

Can be extended via MAP-REFERENCES-OF-TYPE and *map-definitions-of-name*.

- **[macro] `with-definitions-cached`** (*&key* (*dtype* "top")) *&body* *body*

Allow caching of definition lookups and *dtype* computations. This can provide a speedup when multiple calls are made to *definitions* or *dref-*apropos** within *body*.

Using this macro makes the promise that, during the *dynamic extent* of *body*, the following are unchanged:

- the set of *definitions* of *dtype*,

- the set of all [locative types](#),
- the set of all [dtypes](#).

Note that definitions *not* of dtype are allowed to be made or deleted.

- **[function]** `sort-references` *references &key key*

Order references in an implementation independent way.

- Non-symbol named references go first and are [sorted by the locative type](#) first, then by name and locative args.
- Symbol-based references go after and are sorted by name first, then [by the locative-type](#), finally by the locative args.

- **[function]** `sort-locative-types` *locative-types*

Sort locative-types in an implementation independent way. The order is alphabetical in [symbol-name](#), with the [package-name](#) acting as a tie breaker. If unknown is present among locative-types, it goes last.

- **[glossary-term]** `reverse definition order`

The lists of [locative types](#) returned by e.g. [locative-types](#), [lisp-locative-types](#), [pseudo-locative-types](#) and [locative-aliases](#) are in reverse order of the time of their definition. This order is not affected by redefinition, regardless of whether it's by [define-locative-type](#), [define-pseudo-locative-type](#), [define-symbol-locative-type](#) or [define-locative-alias](#).

- **[function]** `locative-types`

Return a list of non-[alias](#) locative types. This is the [union](#) of [lisp-locative-types](#) and [pseudo-locative-types](#), which is the set of constituents of the dtype [top](#).

This list is in [reverse definition order](#).

- **[function]** `lisp-locative-types`

Return the locative types that correspond to Lisp definitions, which typically have [source-location](#). These are defined with [define-locative-type](#) and [define-symbol-locative-type](#) and are the constituents of dtype [t](#).

This list is in [reverse definition order](#).

- **[function]** `pseudo-locative-types`

Return the locative types that correspond to non-Lisp definitions. These are the ones defined with [define-pseudo-locative-type](#) and are the constituents of dtype [pseudo](#).

This list is in [reverse definition order](#).

- **[function]** `locative-aliases`

Return the list of locatives aliases, defined with [define-locative-alias](#).

This list is in [reverse definition order](#).

## 6 Basic Operations

The following functions take a single argument, which may be a [dref](#), or an object denoting its own definition (see [locate](#)).

- **[function]** `arglist` *object*

Return the arglist of the definition of *object* or `nil` if the arglist cannot be determined.

The second return value indicates whether the arglist has been found. As the second return value, `:ordinary` indicates an [ordinary lambda list](#), `:macro` a [macro lambda list](#), `:deftype` a [deftype lambda list](#), and `:destructuring` a [destructuring lambda list](#). Other non-`nil` values are also allowed.

```
(arglist #'arglist)
=> (OBJECT)
=> :ORDINARY
```

```
(arglist (dref 'define-locative-type 'macro))
=> (LOCATIVE-TYPE-AND-LAMBDA-LIST LOCATIVE-SUPERTYPES &OPTIONAL
   DOCSTRING DREF-DEFCLASS-FORM)
=> :MACRO
```

```
(arglist (dref 'arglist* '(method (method-dref))))
=> ((DREF METHOD-DREF))
=> :SPECIALIZED
```

```
(arglist (dref 'method 'locative))
=> (&REST QUALIFIERS-AND-SPECIALIZERS)
=> :DESTRUCTURING
```

This function supports [macros](#), [compiler-macros](#), [setf](#) functions, [functions](#), [generic-functions](#), [methods](#), [types](#), [locatives](#). Note that `arglist` depends on the quality of `swank-backend:arglist`. With the exception of SBCL, which has perfect support, all Lisp implementations have minor omissions:

- [deftype](#) lambda lists on ABCL, AllegroCL, CLISP, CCL, CMUCL, ECL;
- default values in [macro](#) lambda lists on AllegroCL;
- various edge cases involving traced functions.

Can be extended via [arglist\\*](#).

- **[function]** `arglist-parameters` *arglist &optional (arglist-type :ordinary)*

A utility to extract the names of the parameters from `arglist` of `arglist-type`. See the function [arglist](#), for the possible values of `arglist-type`.

Note that if `arglist` is `nil`, then `arglist-type` may also be `nil`, in which case `nil` is returned.

```
(arglist #'source-location)
=> (OBJECT &KEY ERROR)
=> :ORDINARY
```

```
(multiple-value-call 'arglist-parameters (arglist #'source-location))
=> (OBJECT ERROR)
```

Can be extended via `arglist-parameters*`.

- **[function]** `docstring` *object*

Return the docstring from the definition of *object*. As the second value, return the *\*package\** that was in effect when the docstring was installed or `nil` if it cannot be determined (this is used by `pax:document` when determining the Package and Readtable of docstrings). This function is similar in purpose to `cl:documentation`.

Note that some locative types such as `asdf:systems` and `declarations` have no docstrings, and some Lisp implementations do not record all docstrings. The following are known to be missing:

- `compiler-macro` docstrings on ABCL, AllegroCL, CCL, ECL;
- `method-combination` docstrings on ABCL, AllegroCL.

Can be extended via `docstring*`.

- **[function]** `source-location` *object &key error*

Return the Swank source location for the *defining form* of *object*.

The returned Swank location object is to be accessed only through the [Source Locations](#) API or to be passed to e.g Slime's `slime-goto-source-location`.

If no source location was found,

- if *error* is `nil`, then return `nil`;
- if *error* is `:error`, then return a list of the form `(:error <error-message>)` suitable for `slime-goto-source-location`;
- if *error* is `t`, then signal an *error* condition with the same error message as in the previous case.

Note that the availability of source location information varies greatly across Lisp implementations.

With the `nil` *backend*, `dref:source-location` loses precision beyond toplevel forms.

Can be extended via `source-location*`.

## 7 Basic Locative Types

The following are the *locative types* supported out of the box. Like all locative types, they are named by symbols. When there is a CL type corresponding to the reference's locative type, the

references can be [resolved](#) to a unique object as is the case in

```
(resolve (dref 'print 'function))  
==> #<FUNCTION PRINT>  
=> T
```

Even if there is no such CL type, the [arglist](#), the [docstring](#), and the [source-location](#) of the defining form is usually recorded unless otherwise noted.

The basic locative types and their inheritance structure is loosely based on the doc - type argument of [cl:documentation](#).

## 7.1 Locatives for Variables

- **[locative] [variable](#)** *&optional initform*

- Direct locative subtypes: concept, glossary-term, section, [constant](#)

Refers to a global special variable. *initform*, or if not specified, the global value of the variable is to be used for [presentation](#).

```
(dref '*print-length* 'variable)  
==> #<DREF *PRINT-LENGTH* VARIABLE>
```

*variable* references do not [resolve](#).

- **[locative] [constant](#)** *&optional initform*

- Direct locative supertypes: [variable](#)

Refers to a constant variable defined with [defconstant](#). *initform*, or if not specified, the value of the constant is included in the documentation. The [constant](#) locative is like the [variable](#) locative, but it also checks that its object is [constantp](#).

*constant* references do not [resolve](#).

## 7.2 Locatives for Macros

- **[locative] [setf](#)**

- Direct locative subtypes: [setf-method](#), [setf-function](#)

Refers to a [setf expander](#) (see [defsetf](#) and [define-setf-expander](#)).

[Setf functions](#) (e.g. `(defun (setf name) ...)` or the same with [defgeneric](#)) are handled by the [setf-function](#), [setf-generic-function](#), and [setf-method](#) locatives.

*setf expander* references do not [resolve](#).

- **[locative] [macro](#)**

Refers to a global macro, typically defined with [defmacro](#), or to a [special operator](#).

*macro* references resolve to the [macro-function](#) of their name or signal `resolve-error(0 1)` if that's `nil`.

- [locative] **symbol-macro**

Refers to a global symbol macro, defined with `define-symbol-macro`. Note that since `define-symbol-macro` does not support docstrings, PAX defines methods on the documentation generic function specialized on `(doc-type (eql 'symbol-macro))`.

```
(define-symbol-macro my-mac 42)
(setf (documentation 'my-mac 'symbol-macro)
      "This is MY-MAC.")
(documentation 'my-mac 'symbol-macro)
=> "This is MY-MAC."
```

`symbol-macro` references do not `resolve`.

- [locative] **compiler-macro**

- Direct locative subtypes: `setf-compiler-macro`

Refers to a `compiler-macro-function`, typically defined with `define-compiler-macro`.

- [locative] **setf-compiler-macro**

- Direct locative supertypes: `compiler-macro`

Refers to a compiler macro with a `setf function name`.

`setf-compiler-macro` references do not `resolve`.

### 7.3 Locatives for Functions and Methods

- [locative] **function**

- Direct locative subtypes: `structure-accessor`, `setf-function`, `generic-function`

Refers to a global function, typically defined with `defun`. The `name` must be a `function name`. It is also allowed to reference `generic-functions` as functions:

```
(dref 'docstring 'function)
==> #<DREF DOCSTRING FUNCTION>
```

- [locative] **setf-function**

- Direct locative supertypes: `function`, `setf`
- Direct locative subtypes: `structure-accessor`, `setf-generic-function`

Refers to a global `function(0 1)` with a `setf function name`.

```
(defun (setf ooh) ())
(locate #'(setf ooh))
==> #<DREF 00H SETF-FUNCTION>
(dref 'ooh 'setf-function)
==> #<DREF 00H SETF-FUNCTION>
(dref '(setf ooh) 'function)
==> #<DREF 00H SETF-FUNCTION>
```

- **[locative] generic-function**

- Direct locative supertypes: [function](#)
- Direct locative subtypes: [setf-generic-function](#)

Refers to a **generic-function**, typically defined with **defgeneric**. The **name** must be a **function name**.

- **[locative] setf-generic-function**

- Direct locative supertypes: [generic-function](#), [setf-function](#)

Refers to a global **generic-function** with a **setf function name**.

```
(defgeneric (setf oog) ())
(locate #'(setf oog))
==> #<DREF 00G SETF-GENERIC-FUNCTION>
(dref 'oog 'setf-function)
==> #<DREF 00G SETF-GENERIC-FUNCTION>
(dref '(setf oog) 'function)
==> #<DREF 00G SETF-GENERIC-FUNCTION>
```

- **[locative] method** *&rest qualifiers-and-specializers*

- Direct locative subtypes: [writer](#), [reader](#), [setf-method](#)

Refers to a **method**. **name** must be a **function name**. **method-qualifiers-and-specializers** has the form

```
(<QUALIFIER>* <SPECIALIZERS>)
```

For example, the method

```
(defgeneric foo-gf (x y z)
  (:method :around (x (y (eq1 'xxx)) (z string))
    (values x y z)))
```

can be referred to as

```
(dref 'foo-gf '(method :around (t (eq1 xxx) string)))
==> #<DREF F00-GF (METHOD :AROUND (T (EQL XXX) STRING))>
```

**method** is not exportable-locative-type-p.

- **[locative] setf-method** *&rest method-qualifiers-and-specializers*

- Direct locative supertypes: [method](#), [setf](#)
- Direct locative subtypes: [accessor](#)

Refers to a **method** of a **setf-generic-function**.

```
(defgeneric (setf oog) (v)
  (:method ((v string))))
(locate (find-method #'(setf oog) ()) (list (find-class 'string))))
==> #<DREF 00G (SETF-METHOD (STRING))>
```

```
(dref 'oog '(setf-method (string)))
==> #<DREF 00G (SETF-METHOD (STRING))>
(dref '(setf oog) '(method (string)))
==> #<DREF 00G (SETF-METHOD (STRING))>
```

- **[locative]** **method-combination**

Refers to a **method-combination**, defined with **define-method-combination**.

**method-combination** references do not **resolve**.

- **[locative]** **reader** *class-name*

- Direct locative supertypes: **method**

- Direct locative subtypes: **accessor**

Refers to a **:reader** method in a **defclass**:

```
(defclass foo ()
  ((xxx :reader foo-xxx)))

(dref 'foo-xxx '(reader foo))
==> #<DREF F00-XXX (READER F00)>
```

- **[locative]** **writer** *class-name*

- Direct locative supertypes: **method**

- Direct locative subtypes: **accessor**

Like **accessor**, but refers to a **:writer** method in a **defclass**.

- **[locative]** **accessor** *class-name*

- Direct locative supertypes: **reader**, **writer**, **setf-method**

Refers to an **:accessor** in a **defclass**.

An **:accessor** in **defclass** creates a reader and a writer method. Somewhat arbitrarily, **accessor** references **resolve** to the writer method but can be **located** with either.

- **[function]** **accessor-slot-definition** *dref*

Return the **SLOT-DEFINITION** object corresponding to **dref**, which may denote a reader, a writer or an accessor.

- **[locative]** **structure-accessor** *&optional structure-class-name*

- Direct locative supertypes: **setf-function**, **function**

Refers to an accessor function generated by **defstruct** or **defstruct\***. A **locate-error** condition is signalled if the wrong **structure-class-name** is provided.

Note that there is no portable way to detect structure accessors, and on some platforms, **(locate #'my-accessor)**, **definitions** and **dref-apropos** will return **function(0 1)** references instead. On such platforms, **structure-accessor** references do not **resolve**.

- **[macro] `defstruct*`** *name-and-options &rest slot-descriptions*

Like `defstruct`, but support `:documentation` among slot options. The documentation is attached to the slot's structure-accessor. Example:

```
(defstruct* my-struct
  (my-slot nil :documentation "docstring"))
```

In addition to the normal `defstruct` processing, the above also does the moral equivalent of

```
(setf (documentation 'my-struct-my-slot 'function) "docstring")
```

## 7.4 Locatives for Types and Declarations

- **[locative] `type`**
  - Direct locative subtypes: `class`

This locative can refer to **types and classes** as well as **conditions**, simply put, to things defined by `deftype`, `defclass` and `define-condition`.

```
(deftype my-type () t)
(dref 'my-type 'type)
==> #<DREF MY-TYPE TYPE>
```

```
(dref 'xref 'type)
==> #<DREF XREF CLASS>
```

```
(dref 'locate-error 'type)
==> #<DREF LOCATE-ERROR CONDITION>
```

type references do not **resolve**.

- **[locative] `class`**
  - Direct locative supertypes: `type`
  - Direct locative subtypes: `condition`, `structure`

Naturally, `class` is the locative type for **classes**.

`arglist` returns the **compound type specifier** syntax associated with **system classes**. E.g. for the `integer` class:

```
(arglist (find-class 'integer))
=> (&OPTIONAL LOWER-LIMIT UPPER-LIMIT)
=> :DEFTYPE
```

- **[locative] `structure`**
  - Direct locative supertypes: `class`

Refers to a **structure-class**, typically defined with `defstruct`.

Also, see `defstruct*`.

- **[locative] declaration**

Refers to a declaration, used in `declare`, `declaim` and `proclaim`.

User code may also define new declarations with CLTL2 functionality, but their `arglist` is always `nil`. On implementations that support it, `docstring` returns (documentation name 'declaration).

```
(cl-environments:define-declaration my-decl (&rest things)
  (values :declare (cons 'foo things)))
```

declaration references do not `resolve`.

Also, `source-location` on declarations currently only works on SBCL.

## 7.5 Locatives for the Condition System

- **[locative] condition**

- Direct locative supertypes: `class`

Although `condition` is not `subtypep` of `class`, actual condition objects are commonly instances of a condition class that is a CLOS class. HyperSpec [ISSUE:CLOS-CONDITIONS](#) and [ISSUE:CLOS-CONDITIONS-AGAIN](#) provide the relevant history.

Whenever a `class` denotes a condition, its `dref-locative-type` will be `condition`:

```
(dref 'locate-error 'class)
==> #<DREF LOCATE-ERROR CONDITION>
```

- **[locative] restart**

A locative to refer to the definition of a restart defined by `define-restart`.

- **[macro] define-restart** *symbol lambda-list &body docstring*

Associate a definition with the name of a restart, which must be a symbol. `lambda-list` should be what calls like `(invoke-restart '<symbol> ...)` must conform to, but this is not enforced.

PAX "defines" standard CL restarts such as `use-value(0 1)` with `define-restart`:

```
(dref 'use-value 'restart)
==> #<DREF USE-VALUE RESTART>
(assert (docstring *))
(assert (source-location **))
```

Note that while there is a `cl:restart` class, its *instances* have no `docstring` or `source location`.

## 7.6 Locatives for Packages and Readtables

- **[locative] asdf/system:system**

Refers to an already loaded `asdf:system` (those in `asdf:registered-systems`). The `name` may be anything `asdf:find-system` supports.

`asdf:system` is not `exportable-locative-type-p`.

- **[locative] package**

Refers to a `package`, defined by `defpackage` or `make-package`. The `name` may be anything `find-package` supports.

`package` is not `exportable-locative-type-p`.

- **[locative] readtable**

Refers to a named `readtable` defined with `named-readtables:defreadtable`, which associates a global name and a docstring with the readtable object. The `name` may be anything `find-readtable` supports.

`readtable` references `resolve` to `find-readtable` on their `name`.

## 7.7 Locatives for Unknown Definitions

- **[locative] unknown** *dspec*

This locative type allows PAX to work in a limited way with definition types it doesn't know. `unknown` definitions come from `definitions`, which uses `swank/backend:find-definitions`. The following examples show PAX stuffing the Swank `dspec` (`:define-alien-type double-float`) into an `unknown` locative on SBCL.

```
(definitions 'double-float)
==> (#<DREF DOUBLE-FLOAT CLASS>
--> #<DREF DOUBLE-FLOAT (UNKNOWN (:DEFINE-ALIEN-TYPE DOUBLE-FLOAT))>)
```

```
(dref 'double-float '(unknown (:define-alien-type double-float)))
==> #<DREF DOUBLE-FLOAT (UNKNOWN (:DEFINE-ALIEN-TYPE DOUBLE-FLOAT))>
```

`arglist` and `docstring` return `nil` for unknowns, but `source-location` works.

## 7.8 Locatives for DRef Constructs

- **[locative] dtype**

- Direct locative subtypes: `locative`

Locative for `dtypes` defined with `define-dtype` and `locative` types. `dtype` is to `locative` as `type` is to `class`.

The `top` of the `dtype` hierarchy:

```
(dref 'top 'dtype)
==> #<DREF TOP DTYPE>
```

This very definition:

```
(dref 'dtype 'locative)
==> #<DREF DTYPE LOCATIVE>
```

- **[locative]** **locative**

- Direct locative supertypes: [dtype](#)

This is the locative for [locative](#) types defined with [define-locative-type](#), [define-pseudo-locative-type](#) and [define-locative-alias](#).

```
(first-line (source-location-snippet
              (source-location (dref 'macro 'locative))))
=> "(define-locative-type macro ())"
```

- **[locative]** **lambda** *&key arglist arglist-type docstring docstring-package file file-position snippet &allow-other-keys*

A [pseudo locative type](#) that carries its [arglist](#), [docstring](#) and [source-location](#) in the locative itself. See [make-source-location](#) for the description of [file](#), [file-position](#), and [snippet](#). [lambda](#) references do not [resolve](#). The [name](#) must be `nil`.

```
(arglist (dref nil '(lambda :arglist ((x y) z)
                        :arglist-type :macro)))
=> ((X Y) Z)
=> :MACRO
```

```
(docstring (dref nil '(lambda :docstring "xxx"
                              :docstring-package :dref)))
=> "xxx"
==> #<PACKAGE "DREF">
```

```
(source-location-file
 (source-location (dref nil '(lambda :file "xxx.el"))))
=> "xxx.el"
```

Also, see the `pax:include` locative.

## 8 Backends

On SBCL, the `swank asdf:system` is not a dependency of `dref/full` because `DRef` is able to function without it. However, when `Swank` is available in the Lisp image, `DRef` can use it to provide more precise [source-locations](#).

On other Lisps, `DRef` currently gets [arglists](#) and [source-locations](#) via `Swank` and `swank` is an ASDF dependency of `dref/full`.

- **[function]** **backend-available-p** *backend*

Check if `backend` is currently available in the running Lisp. `backend` may be `:swank` or `nil`. Currently, on SBCL, both are available; on other Lisps, only `:swank` is.

- **[function]** **backend**

Return the backend being used. This is either `:swank` or `nil`. The default backend is `:swank` if it is available when first loading `dref` into the image, else it is `nil`.

Note that on Lisps other than SBCL, this is currently always `:swank`, which is available due to the ASDF dependency of `dref/full` on the `swank asdf:system`.

- **[setf] `backend`** *backend*

setting `backend` to a backend that is not `backend-available-p` is an error.

- **[macro] `with-backend`** (*backend*) &body *body*

Like `setf backend`, but only change backend during the dynamic extent of *body*.

## 9 Extending DRef

### 9.1 Extension Tutorial

Let's see how to tell DRef about new kinds of definitions through the example of the implementation of the `class` locative. Note that this is a verbatim `pax:include` of the sources. Please ignore any internal machinery. The first step is to define the `locative type`:

```
(define-locative-type class (type)
  "Naturally, CLASS is the locative type for [CLASS][class]es.

  ARGUMENTS
  ~~~~~
  ARGLIST returns the [compound type specifier][clhs] syntax
  associated with [system class][clhs]es. E.g. for the [INTEGER][clhs]
  class:

  ~~~~cl-transcript (:dynenv dref-std-env)
  (arglist (find-class 'integer))
  => (&OPTIONAL LOWER-LIMIT UPPER-LIMIT)
  => :DEFTYPE
  ~~~~")
```

Then, we make it possible to look up `class` definitions:

```
(define-locator class ((class class))
  (make-instance 'class-dref :name (class-name class) :locative 'class))

(define-lookup class (symbol locative-args)
  (unless (and (symbolp symbol)
               (find-class symbol nil))
    (locate-error "~S does not name a class." symbol))
  (make-instance 'class-dref :name symbol :locative 'class))
```

`define-locator` makes `(locate (find-class 'dref))` work, while `define-lookup` is for `(dref 'dref 'class)`. Naturally, for locative types that do not define first-class objects, the first method cannot be defined.

Finally, we define a `resolve*` method to recover the `class` object from a `class-dref`. We also specialize `docstring*` and `source-location*`:

```

(defmethod resolve* ((dref class-dref))
  (find-class (dref-name dref)))

(defmethod docstring* ((class class))
  (documentation* class t))

(defmethod source-location* ((dref class-dref))
  #+sbcl
  (sb-one-source-location (dref-name dref) :class)
  #-sbcl
  (swank-source-location* (resolve dref) (dref-name dref) 'class))

(defmethod arglist* ((dref class-dref))
  (clhs-type-specifier-arglist (dref-name dref)))

```

We took advantage of having just made the class locative type being `resolveable`, by specializing `docstring*` on the `class` class. `source-location*` was specialized on `class-dref` to demonstrate how this can be done for non-`resolveable` locative types.

Classes have no arglist, so no `arglist*` method is needed. In the following, we describe the pieces in detail.

## 9.2 Locative Type Hierarchy

`Locative types` form their own hierarchy, that is only superficially similar to the Lisp `class` hierarchy. The hierarchies of `lisp-locative-types` and `pseudo-locative-types` are distinct. That is, the `dref-class` of a Lisp locative type must not be a subclass of a `pseudo` one, and vice versa. This is enforced by `define-locative-type` and `define-pseudo-locative-type`.

- **[function]** `dref-class` *locative-type*

Return the name of the `class` used to represent `definitions` with `locative-type`. This is always a subclass of `dref`. Returns `nil` if `locative-type` is not a valid locative type.

Note that the actual `type-of` a `dref` is mostly intended for `Extending DRef`. Hence, it is hidden when a `dref` is printed:

```

(dref 'print 'function)
==> #<DREF PRINT FUNCTION>
(type-of *)
=> FUNCTION-DREF

```

Due to `Canonicalization`, the actual type may be a proper subtype of `dref-class`:

```

(dref 'documentation 'function)
==> #<DREF DOCUMENTATION GENERIC-FUNCTION>
(type-of *)
=> GENERIC-FUNCTION-DREF
(subtypep 'generic-function-dref 'function-dref)
=> T
=> T

```

- **[function]** `locative-type-direct-supers` *locative-type*

List the [locative types](#) whose [dref-classes](#) are direct superclasses of the `dref-class` of `locative-type`. These can be considered supertypes of `locative-type` in the sense of [dtypep](#).

This is ordered as in the corresponding definition.

- **[function]** `locative-type-direct-subs` *locative-type*

List the [locative types](#) whose [dref-classes](#) are direct subclasses of the `dref-class` of `locative-type`. These can be considered subtypes of `locative-type` in the sense of [dtypep](#).

This list is in [reverse definition order](#).

- **[function]** `locative-subtype-p` *locative-type-1 locative-type-2*

Check if `locative-type-1` is in the transitive closure of `locative-type-2` via [locative-type-direct-subs](#). It is an error if `locative-type-1` or `locative-type-2` is not a valid locative type.

### 9.3 Defining Locative Types

- **[macro]** `define-locative-type` *locative-type-and-lambda-list locative-supertypes &optional docstring dref-defclass-form*

Declare `locative-type` as a [locative](#), which is the first step in [Extending DRef](#).

- *Simple example*

To define a locative type called `dummy` that takes no arguments and is not a locative subtype of any other locative type:

```
(define-locative-type dummy ()
  "Dummy docstring.")
```

With this definition, only the locatives `dummy` and its equivalent form `(dummy)` are valid. The above defines a `dref(0 1)` subclass called `dummy-dref` in the current package. All definitions with locative type `dummy` and its locatives subtypes must be instances of `dummy-dref`.

`(locate 'dummy 'locative)` refers to this definition. That is, [arglist](#), [docstring](#) and [source-location](#) all work on it.

- *Complex example*

`dummy` may have arguments `x` and `y` and inherit from locative types `l1` and `l2`:

```
(define-locative-type (dummy x &key y) (l1 l2)
  "Dummy docstring."
  (defclass dummy-dref ()
    ((xxx :initform nil :accessor dummy-xxx))))
```

One may change name of dummy-dref, specify superclasses and add slots as with `defclass`. Behind the scenes, the dref classes of `l1` and `l2` are added automatically to the list of superclasses.

Arguments:

- The general form of `locative-type-and-lambda-list` is `(locative-type &rest lambda-list)`, where `locative-type` is a `symbol`, and `lambda-list` is a `destructuring lambda list`. The `locative-args` of drefs with `locative type` `locative-type` (the argument given to this macro) always conform to this lambda list. See `check-locative-args`.

If `locative-type-and-lambda-list` is a single symbol, then that's interpreted as `locative-type`, and `lambda-list` is `nil`.

- `locative-supertypes` is a list of `locative types` whose `dref-classes` are prepended to the list of superclasses this definition.

Locative types defined with `define-locative-type` can be listed with `lisp-locative-types`.

- **[macro] `define-pseudo-locative-type`** *locative-type-and-lambda-list locative-supertypes &optional docstring dref-defclass-form*

Like `define-locative-type`, but declare that `locative-type` does not correspond to definitions in the running Lisp. Definitions with pseudo locatives are of dtype `pseudo` and are not listed by default by `definitions`.

Locative types defined with `define-pseudo-locative-type` can be listed with `pseudo-locative-types`.

- **[macro] `define-locative-alias`** *alias locative-type &body docstring*

Define `alias` that can be substituted for `locative-type` (both `symbols`) for the purposes of `locateing`. `locative-type` must exist (i.e. be among `locative-types`). For example, let's define `object` as an alias of the `class` `locative`:

```
(define-locative-alias object class)
```

Then, `locateing` with `object` will find the `class`:

```
(dref 'xref 'object)
==> #<DREF XREF CLASS>
```

The `locative-args` of `object` (none in the above) are passed on to `class`.

```
(arglist (dref 'object 'locative))
=> (&REST ARGS)
=> :DESTRUCTURING
```

Note that `locative-aliases` are not `locative-types` and are not valid dtypes.

Also, see `Locative Aliases` in `PAX`.

### 9.3.1 Symbol Locatives

Let's see how the opaque `define-symbol-locative-type` and the obscure `define-definer-for-symbol-locative-type` macros work together to simplify the common task of associating definition with a symbol in a certain context.

- **[macro] `define-symbol-locative-type`** *locative-type-and-lambda-list locative-supertypes &optional docstring dref-class-def*

Similar to `define-locative-type`, but it assumes that all things `locateable` with `locative-type` are going to be symbols defined with a definer defined with `define-definer-for-symbol-locative-type`. Symbol locatives are for attaching a definition (along with arglist, documentation and source location) to a symbol in a particular context. An example will make everything clear:

```
(define-symbol-locative-type direction ()  
  "A direction is a symbol.")  
  
(define-definer-for-symbol-locative-type define-direction direction  
  "With DEFINE-DIRECTION, one can document what a symbol means when  
  interpreted as a DIRECTION.")  
  
(define-direction up ()  
  "UP is equivalent to a coordinate delta of (0, -1).")
```

After all this, `(dref 'up 'direction)` refers to the `define-direction` form above.

The `dref-class` of the defined locative type inherits from `symbol-locative-dref`, which may be used for specializing when implementing new operations.

- **[macro] `define-definer-for-symbol-locative-type`** *name locative-type &body docstring*

Define a macro with `name` that can be used to attach a lambda list, documentation, and source location to a symbol in the context of `locative-type`. The defined macro's arglist is `(symbol lambda-list &optional docstring)`. `locative-type` is assumed to have been defined with `define-symbol-locative-type`.

## 9.4 Extending `locate`

Internally, `locate` finds an initial `dref` of its object argument with a `lookup` or with a `locator`. This initial `dref` is then canonicalized with a series of `casts`. In more detail, the process is as follows.

- If the object argument of `locate` is a `dref`, then it is returned without processing.

Else, `locate` first needs to find the initial definition.

### 9.4.1 Initial Definition

`locate` can find the initial definition in one of two ways:

- *With direct lookup*

If object is an `xref(0 1)`, then the `lookup` for (`xref-locative-type` object) is invoked. For an `xref` with the locative (`method (number)`), this would be the lookup defined as

```
(define-lookup method (name locative-args) ...)
```

- *With locator search*

Else, object is a normal Lisp object, such as a `method` object from `find-method`. The first of `lisp-locative-types` whose `locator` succeeds provides the initial definition, which may be defined like this:

```
(define-locator method ((obj method)) ...)
```

This is a locator that returns definitions with the `method` locative type and takes an argument named `obj` of class `method` (which is like a `specializer` in `defmethod`).

- `lisp-locative-types` are tried one by one in the order specified there.
- For a given locative type, if there are multiple locators, standard CLOS method selection applies.

## 9.4.2 Canonicalization

The initial definition thus found is then canonicalized so that there is a unique `definition` under `xref=`:

```
(locate #'arglist*)  
==> #<DREF ARGLIST* GENERIC-FUNCTION>  
(dref 'arglist* 'function)  
==> #<DREF ARGLIST* GENERIC-FUNCTION>  
(dref 'arglist* 'generic-function)  
==> #<DREF ARGLIST* GENERIC-FUNCTION>
```

Canonicalization is performed by recursively attempting to `downcast` the current definition to one of its `locative-type-direct-subs` in a depth-first manner, backtracking if a cast fails.

**Default Downcast** By default, downcasting to `direct locative subtypes` is performed by looking up the definition where the locative type is replaced with its sub while the name and the locative args remain the same.

**Cast Name Change** `Casts` must be careful about changing `dref-name`.

Their `dref` argument and the `dref` returned must have the same `dref-name` (under `equal`, see `xref=`) or it must be possible to upcast the returned value to the `dref` argument's `dref-locative-type`.

- *Implementation note*

The purpose of this rule is to allow `dtypep` answer this correctly:

```
(defclass foo ()  
  ((a :accessor foo-a)))
```

```

(dref '(setf foo-a) '(method (t foo)))
==> #<DREF F00-A (ACCESSOR F00)>
(dtypep * '(method (t foo)))
=> T
;; Internally, DTYPEP upcast #<DREF F00-A (ACCESSOR F00)>
;; and checks that the locative args of the resulting
;; definition match those in (METHOD (T F00)).
(locate* ** 'method)
==> #<DREF (SETF F00-A) (METHOD (T F00))>

```

For even more background, also note that if the name remains the same but locative args change, then `dtypep` can simply check with `dref` if there is a definition of the name with the given locative:

```

(defclass foo ()
  ((r :reader foo-r)))
(dref 'foo-r '(reader foo))
==> #<DREF F00-R (READER F00)>
(dtypep * '(method (foo)))
=> T
;; Behind the scenes, DTYPEP does this:
(xref= ** (dref 'foo-r '(method (foo))))
=> T

```

### 9.4.3 Defining Lookups, Locators and Casts

As we have seen, the [Initial Definition](#) is provided either by a lookup or a locator, then [Canonicalization](#) works with casts. Here, we look at how to define these.

*Implementation note:* All three are currently implemented as methods of generic functions with [eql specializers](#) for the locative type, which may easily prove to be problematic down the road. To make future changes easier, the generic function and the methods are hidden behind e.g. the `define-lookup` and `call-lookup` macros.

- **[variable]** `*check-locate*` *nil*

Enable runtime verification of invariants during `locate` calls. This carries a performance penalty and is intended for testing and debugging.

In particular, enforce the rule of [Cast Name Change](#) and that [lookups](#), [locators](#) and [casts](#) obey the following:

- The value returned must be either `nil` or a `dref(0 1)`. Alternatively, `locate-error(0 1)` may be signalled.
- If a `dref` is returned, then its `dref-locative-type` must be `locative-type`, and its class must be the `dref-class` of `locative-type`.
- `locative-args` must be congruent with the destructuring lambda list in the definition of `locative-type`.

- **[macro]** `define-lookup` *locative-type (name locative-args) &body body*

Define a method of looking up [definitions](#) of `locative-type` with the given `locative-args`. Lookups are invoked by `locate` when its object argument is an `xref(0 1)` with `locative-type` but it is not a `dref(0 1)`, as in the case of `(dref 'print 'function)`. When called, the variables `name` and `locative-args` are bound to `xref-name` and `xref-locative-args` of the `xref`. `locative-args` is validated with `check-locative-args` before body is evaluated.

```
(define-lookup variable (name locative-args)
  (unless (special-variable-name-p name)
    (locate-error))
  (make-instance 'variable-dref :name name :locative 'variable))
```

- `locative-type` is a valid [locative type](#).
- `name` and `locative-args` are both [symbols](#).

The above are enforced at macro-expansion time.

- body must follow the rules in `*check-locate*`.

- **[macro] `call-lookup`** *name locative-type locative-args*

Call the [lookup](#) for `locative-type` with `name` and `locative-args`.

- **[macro] `define-locator`** *locative-type ((object class)) &body body*

Define a method of finding the [definition](#) with `locative-type` of instances of `class`. When a locator's body is evaluated, `object` is bound to such an instance.

```
(define-locator class ((class class))
  (make-instance 'class-dref :name (class-name class) :locative 'class))
```

- `locative-type` is one of [lisp-locative-types](#). This is because [pseudo-locative-types](#) never [resolve](#) to first-class objects.
- `object` is a [symbol](#).
- `class` names a [class](#) that is not a subtype of `xref`. For how to convert definitions from one `locative-type` to another, see [define-cast](#).

The above are enforced at macro-expansion time.

- body must follow the rules in `*check-locate*`.

In contrast to when the [Initial Definition](#) is created from an `xref` (see [define-lookup](#)), here `locative-args` are determined from `object`.

- **[macro] `call-locator`** *object locative-type*

Call the [locator](#) for `locative-type` with `object`.

- **[macro] `define-cast`** *locative-type ((dref dref-class)) &body body*

Define a method of converting a [definition](#) to another with `locative-type`. When a cast's body is evaluated, `dref` is bound to an instance `dref-class`, which denotes a valid but potentially [non-canonical](#) definition.

Note that the [Default Downcast](#) often suffices, and defining a cast is only necessary if the [name](#) or the [locative args](#) change:

```
(define-cast accessor ((dref reader-dref))
  (let ((name (dref-name dref))
        (class (second (dref-locative dref))))
    (when (ignore-errors (find-accessor-slot-definition name class))
      (make-instance 'accessor-dref :name name
                        :locative `(accessor ,class)))))
```

- [locative-type](#) is a valid [locative type](#).
  - If [locative-type](#) is one of [pseudo-locative-types](#), then [dref-class](#) must be of another pseudo [locative type](#).
  - [dref-class](#) is either a direct *downcast* or a potentially non-direct *upcast*.
    - \* *Downcast*: In this case, [locative-type](#) is one of [locative-type-direct-sub](#)s of ([dref-class-to-locative-type](#) [dref-class](#)).
- Downcasting to non-direct subtypes is done in multiple steps. Consequently, the body of a downcast can rely on ([class-of](#) [dref](#)) being [class](#), not any subclass thereof.
- \* *Upcast*: [locative-type](#) is different but reachable from ([dref-class-to-locative-type](#) [dref-class](#)) by repeatedly choosing one of [locative-type-direct-supers](#). Upcasting to non-direct supertypes is done in one step.

The above are enforced at macro-expansion time.

- body must follow the rules in [\\*check-locate\\*](#), including those in [Cast Name Change](#).
- **[macro]** `call-cast` *locative-type dref*  
Call the [cast](#) to [locative-type](#) with [dref](#).
  - **[function]** `locate-error` *&optional format-control &rest format-args*  
Call this function to signal a [locate-error](#) condition from the [dynamic extent](#) of a [locate](#) call, that is, from the bodys of [define-lookup](#), [define-locator](#) and [define-cast](#). It is an error to call [locate-error](#) elsewhere.  
  
[format-control](#), if non-`nil`, is a [format control](#) for which [format-args](#) are suitable.
  - **[macro]** `check-locative-args` *locative-type locative-args*  
Signal a [locate-error](#) condition if [locative-args](#) do not match the `lambda-list` argument of [locative-type](#) (not evaluated).

## 9.5 Extending Everything Else

- **[generic-function]** `resolve*` *dref*

Return the object defined by the definition `dref` refers to. Signal a `resolve-error` condition by calling the `resolve-error` function if the lookup fails.

To keep `resolve` a partial inverse of `locate`, `define-locator` may be necessary for resolveable definitions. This function is for extending `resolve`. Do not call it directly.

It is an error for methods of this generic function to return an `xref`.

- **[function]** `resolve-error` *&rest format-and-args*

Call this function to signal a `resolve-error` condition from the `dynamic extent` of a `resolve*` method. It is an error to call `resolve-error` elsewhere.

`format-and-args`, if non-`nil`, is a format string and arguments suitable for `format`.

- **[generic-function]** `map-definitions-of-name` *fn name locative-type*

Call `fn` with `drefs` which can be `located` with an `xref(0 1)` with `name`, `locative-type` and some `locative-args`. The strange wording here is because there may be multiple ways (and thus `xrefs`) that refer to the same definition.

For most `locative` types, there is at most one such definition, but for `method`, for example, there may be many. The default method simply does `(dref name locative-type nil)` and calls `fn` with result if `dref` succeeds.

`fn` is not called with the same (under `xref=`) definition multiple times.

- **[generic-function]** `map-definitions-of-type` *fn locative-type*

Call `fn` with `drefs` that can be `located` with an `xref(0 1)` with `locative-type` with some `name` and `locative-args`.

- Return `nil` if all possibilities have been exhausted.
- Return `true` if there may be definitions left unmapped. In this case, the caller is responsible for trying all interned symbols with `map-definitions-of-name`. The default method simply returns `true`.

`fn` may be called with `drefs` that are `xref=` and differ only in their `dref-origin`.

- **[generic-function]** `arglist*` *object*

To extend `arglist`, specialize `object` on a normal Lisp type or on a subclass of `dref`.

`arglist` first calls `arglist*` with its `object` argument. If that doesn't work (i.e. the second value returned is `nil`), then it calls `arglist*` with `object` either `resolved` (if it's a `dref`) or `located` (if it's not a `dref`).

- The default method returns `nil, nil`.
- There is also a method specialized on `drefs`, that looks up the `definition-property` called `arglist` and returns its value with `values-list`. Thus, an `arglist` and its kind can be specified with something like

```
(setf (definition-property xref 'arglist)
      (list arglist :destructuring))
```

This function is for extension only. Do not call it directly.

- **[generic-function]** `arglist-parameters*` *arglist arglist-type*

To extend `arglist-parameters`, *eql(0 1)*-specialize *arglist-type* on, say, *:BOA* (see *BOA lambda lists*). This must be done if *arglist* is extended to return an unsupported value.

This function is for extension only. Do not call it directly.

- **[generic-function]** `docstring*` *object*

To extend `docstring`, specialize *object* on a normal Lisp type or on a subclass of `dref`.

`docstring` first calls `docstring*` with its *object* argument. If that doesn't work (i.e. `nil` is returned), then it calls `docstring*` with *object* either `resolved` (if it's a `dref`) or `located` (if it's not a `dref`).

- The default method returns `nil`.
- A three-stage logic is implemented by an unspecialized `:around` method for docstrings and packages.
  - \* First, the primary method is called. If it returns a non-`nil` docstring and package, then these are returned by `docstring*`.
  - \* *Definition default*: The `definition-property` with indicator `docstring` of the `located` definition of *object* provides defaults for the docstring and/or the package, whichever are `nil`. These can be set for example as

```
(setf (definition-property xref 'docstring)
      (list docstring *package*))
```

Note that the docstring and the package or both may be `nil`.

- \* *Package-wide default*: If the `dref-name` of the `located` definition is a symbol, then an irregular `definition-property` provides further defaults. To default the docstring package of all names of package *x* to package *y*, you could write

```
(setf (definition-property `(:package ,(find-package :x)) 'docstring)
      (list "FIXME: Missing documentation." (find-package :y)))
```

See `Package` and `Readtable`.

This function is for extension only. Do not call it directly.

- **[generic-function]** `source-location*` *object*

To extend `source-location`, specialize *object* on a normal Lisp type or on a subclass of `dref`.

`source-location` first calls `source-location*` with its *object* argument. If that doesn't work (i.e. `nil` or `(:error <message>)` is returned), then it calls `source-location*` with *object* either `resolved` (if it's a `dref`) or `located` (if it's not a `dref`).

`source-location` returns the last of the `(:error <message>)`s encountered or a generic error message if only `nil`s were returned.

- The default method returns `nil`.
- There is also a method specialized on `drefs`, that looks up the `definition-property` called `source-location`. If present, it must be a function of no arguments that returns a source location or `nil`. Typically, this is set up in the defining macro like this:

```
(setf (definition-property xref 'source-location)
      (this-source-location))
```

This function is for extension only. Do not call it directly.

- **[macro]** `nth-value-or-with-obj-or-def` (*obj nth-value*) &body *body*

Evaluate *body*. If its *nth-value* is `nil`, evaluate it again with *obj* bound to a `resolved` object (if *obj* was a definition) or a definition (if *obj* was not a definition). This is intended for implementing new operations with the fallback mechanism of `arglist`, `docstring` and `source-location*`.

### 9.5.1 Definition Properties

Arbitrary data may be associated with definitions. This mechanism is used by `arglist*`, `docstring*` and `source-location*` for easy extension.

The following functions take an `xref` argument and not a `dref(0 1)` to allow working with `non-canonical` or non-existent definitions.

- **[function]** `definition-property` *obj indicator*

Return the value of the property associated with *obj* whose name is `eq(0 1)` to *indicator*. The second return value indicates whether the property was found. `setfable`.

- *Regular definition*: *obj* is commonly an `xref(0 1)`. `xrefs` that are `xref=` are equivalent for the purposes of `definition-property`.
- *Irregular case*: If *obj* is not an `xref` (and, by extension, not a `dref(0 1)`), it is equivalent to other objects to which it is `equal`.

For example, see the `docstring*` generic-function, which uses both the regular and the irregular cases.

- **[function]** `delete-definition-property` *obj indicator*

Delete the property *indicator* of *obj* established by setting `definition-property`. Return true if the property was found.

- **[function]** `definition-properties` *xref*

Return the properties of *xref* as an association list.

- **[function]** `delete-definition-properties` *xref*

Delete all properties associated with *xref*.

- **[function]** `move-definition-properties` *from-xref to-xref*

Associate all properties of `from-xref` with `to-xref`, as if readding them one-by-one with `(setf definition-property)`, and deleting them from `from-xref` with `delete-definition-property`.

## 9.6 dref-classes

These are the `dref-classes` corresponding to [Basic Locative Types](#). They are exported to make it possible to go beyond the [Basic Operations](#) (e.g. `pax:document-object*`). For [Defining Locative Types](#), they are not necessary, as `define-locative-type` handles inheritance automatically based on its `locative-supertypes` argument.

### for Variables

- `[class] variable-dref` *dref*  
`dref-ext:dref-class` of `variable`.
- `[class] constant-dref` *variable-dref*  
`dref-ext:dref-class` of `mgl-pax:constant`.

### for Macros

- `[class] macro-dref` *dref*  
`dref-ext:dref-class` of `mgl-pax:macro`.
- `[class] symbol-macro-dref` *dref*  
`dref-ext:dref-class` of `mgl-pax:symbol-macro`.
- `[class] compiler-macro-dref` *dref*  
`dref-ext:dref-class` of `compiler-macro`.
- `[class] setf-dref` *dref*  
`dref-ext:dref-class` of `setf`.
- `[class] setf-compiler-macro-dref` *compiler-macro-dref*  
`dref-ext:dref-class` of `dref:setf-compiler-macro`.

### for Functions

- `[class] function-dref` *dref*  
`dref-ext:dref-class` of `function`.
- `[class] setf-function-dref` *function-dref setf-dref*  
`dref-ext:dref-class` of `dref:setf-function`.
- `[class] generic-function-dref` *function-dref*  
`dref-ext:dref-class` of `generic-function`.

- [class] `setf-generic-function-dref` *generic-function-dref setf-function-dref*  
dref-ext:dref-class of dref:setf-generic-function.
- [class] `method-dref` *dref*  
dref-ext:dref-class of method.
- [class] `setf-method-dref` *method-dref setf-dref*  
dref-ext:dref-class of dref:setf-method.
- [class] `method-combination-dref` *dref*  
dref-ext:dref-class of method-combination.
- [class] `reader-dref` *method-dref*  
dref-ext:dref-class of mgl-pax:reader.
- [class] `writer-dref` *method-dref*  
dref-ext:dref-class of mgl-pax:writer.
- [class] `accessor-dref` *reader-dref writer-dref setf-method-dref*  
dref-ext:dref-class of mgl-pax:accessor.
- [class] `structure-accessor-dref` *setf-function-dref function-dref*  
dref-ext:dref-class of mgl-pax:structure-accessor.

#### for Types and Declarations

- [class] `type-dref` *dref*  
dref-ext:dref-class of type.
- [class] `class-dref` *type-dref*  
dref-ext:dref-class of class.
- [class] `declaration-dref` *dref*  
dref-ext:dref-class of declaration.

#### for the Condition System

- [class] `condition-dref` *class-dref*  
dref-ext:dref-class of condition.
- [class] `restart-dref` *symbol-locative-dref*  
dref-ext:dref-class of restart.

#### for Packages and Readtables

- [class] `asdf-system-dref` *dref*  
dref-ext:dref-class of asdf/system:system.

- [class] `package-dref` *dref*  
[dref-ext:dref-class](#) of `package`.
- [class] `readtable-dref` *dref*  
[dref-ext:dref-class](#) of `readtable`.

#### for Unknown Definitions

- [class] `unknown-dref` *dref*  
[dref-ext:dref-class](#) of `mgl-pax:unknown`.

#### for DRef Constructs

- [class] `dtype-dref` *dref*  
[dref-ext:dref-class](#) of `dref:dtype`.
- [class] `locative-dref` *dtype-dref*  
[dref-ext:dref-class](#) of `mgl-pax:locative`.
- [class] `symbol-locative-dref` *dref*  
 All `locative` types defined with `define-symbol-locative-type` inherit from this class.
- [class] `lambda-dref` *dref*  
[dref-ext:dref-class](#) of `lambda`.

## 9.7 Source Locations

These represent the file or buffer position of a **defining form** and are returned by the `source-location` function. For the details, see the Emacs function `slime-goto-source-location`.

- [function] `make-source-location` *&key file file-position buffer buffer-position snippet*  
 Make a Swank source location. The ultimate reference is `slime-goto-source-location` in `slime.el`. When `snippet` is provided, the match nearest to `file-position` is determined (see the Emacs `slime-isearch` and `source-location-adjusted-file-position`).
- [function] `source-location-p` *object*  
 See if `object` is a source location object.
- [function] `source-location-file` *location*  
 Return the name of the file of the **defining form**. This may be `nil`, for example, if `location` is of a **defining form** that was entered at the REPL, or compiled in the `*slime-scratch*` buffer.
- [function] `source-location-file-position` *location*  
 Return the file position of the **defining form** or `nil` if it's not available. The first position is 0.

- **[function]** `source-location-buffer` *location*

Return the name of the Emacs buffer of the **defining form** or `nil` if there is no such Emacs buffer.

- **[function]** `source-location-buffer-position` *location*

Return the position of the **defining form** in `source-location-buffer` or `nil` if it's not available. The first position is 1.

- **[function]** `source-location-snippet` *location*

Return the **defining form** or a prefix of it as a string or `nil` if it's not available.

- **[function]** `source-location-adjusted-file-position` *location*

Return the actual file position *location* points to allowing for some deviation from the raw `source-location-file-position`, which is adjusted by searching for the nearest occurrence of `source-location-snippet` in the file. The file is read using the same external format that ASDF would use to compile it. Needless to say, this can be a very expensive operation.

If `source-location-file` is `nil`, `nil` is returned. If there is no snippet, or it doesn't match, then `source-location-file-position` (or 0 if that's `nil`) is returned.

This is a non-interactive companion to the Elisp function `slime-location-offset`, supporting only file positions and non-partial matching of snippets.

- **[macro]** `this-source-location`

The value of this macro form is a function of no arguments that returns its own `source-location`.

## 10 Indices

Referrer definition type abbreviations:

- *f*: for definitions in the function namespace (macros, compiler macros and also methods)
- *t*: DEFTYPEs, classes, conditions, structs
- *d*: documentation sections and glossary terms
- *l*: definitions of definition types
- *s*: ASDF systems
- *p*: packages
- *n*: named readtables
- *v*: special variables and constants
- *r*: restarts
- *?*: other
